

Personality measurement is a theory of human variance

Saucier 525-PDA: 700 human self-ratings on 523 adjectives, aggregated to 44 trait blocks (pole-respecting Ward on the human correlations; coherence-filtered, no size cap — the large blocks are the trait majors: warmth, anxiety, anger, honesty). This block structure is what the Big Five compress.

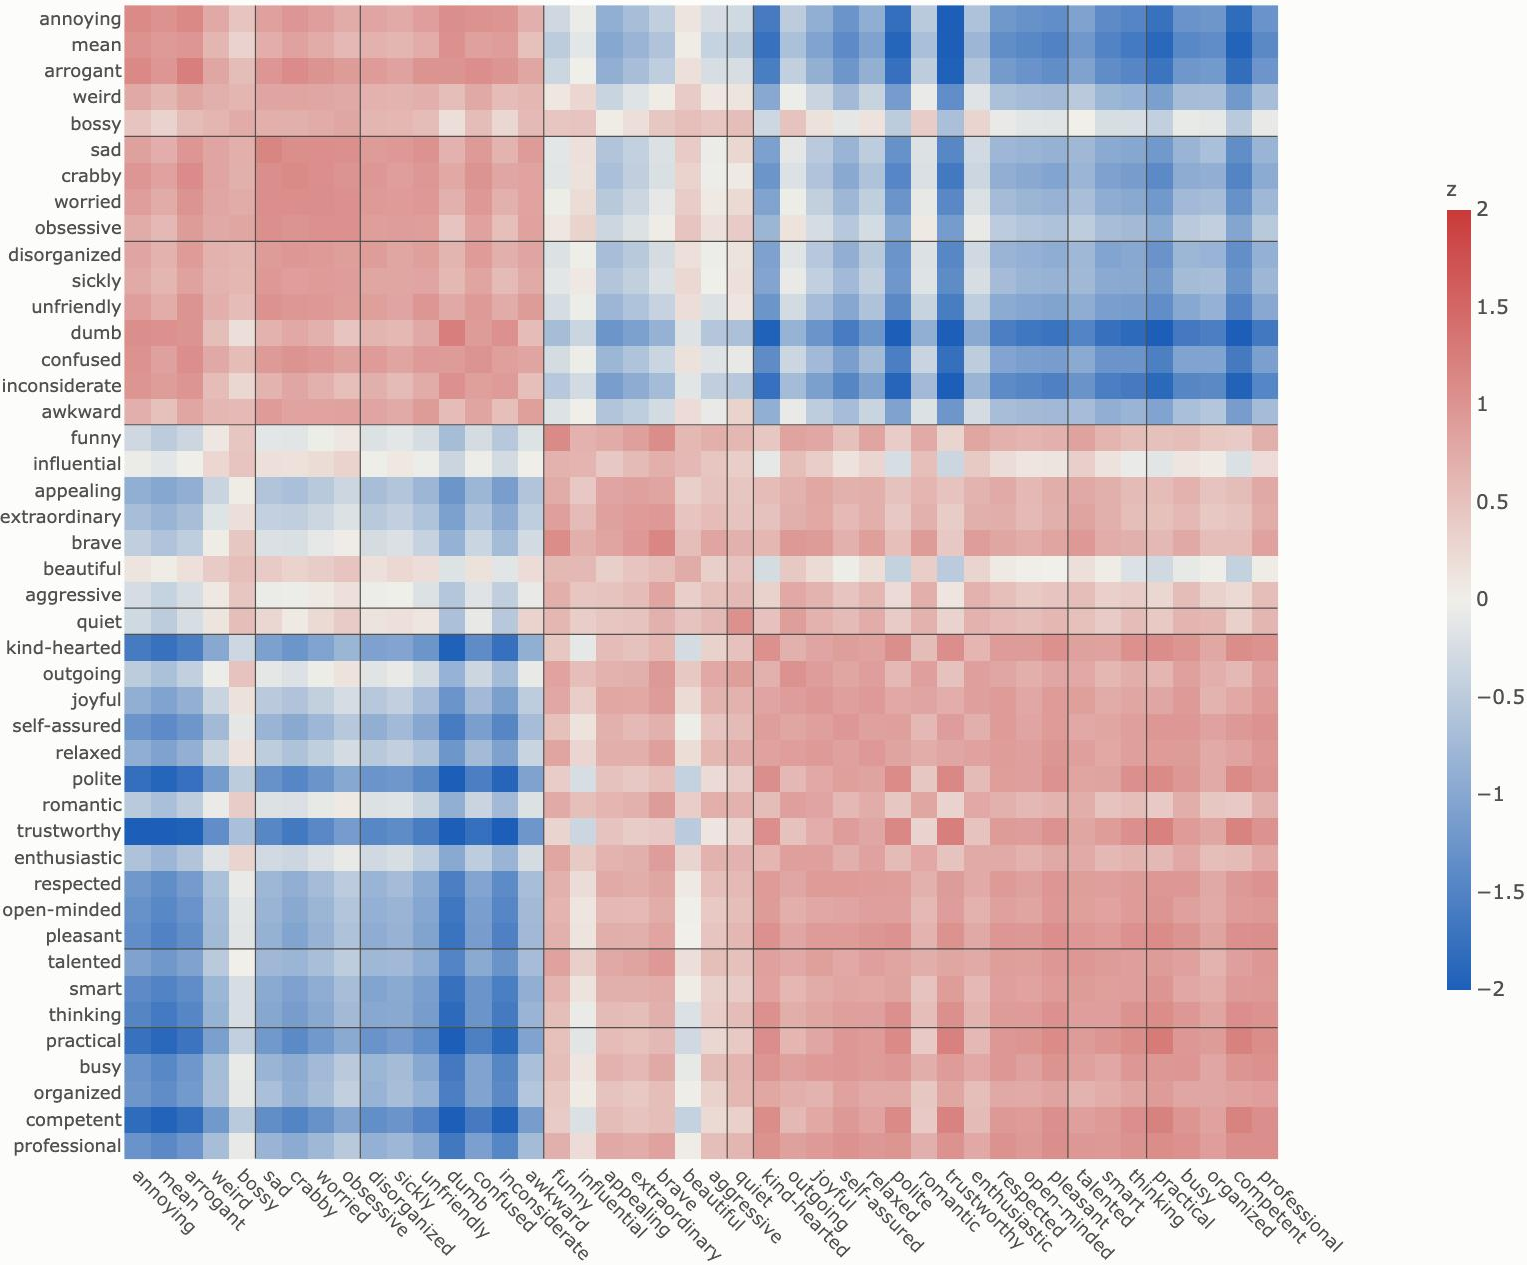

HUMAN

Ask models the same questions: the population is tiny — and not human-shaped

Same construction with models as respondents: n = 65 deployed instruct models (wide-n cohort + standing; 6 framings averaged)
— the correlation estimate is now full-rank at block level. Raw congruence is a desirability freebie; the
top-component-removed number is the honest one.

r(HUMAN) = 0.86 raw | 0.28 with top component removed

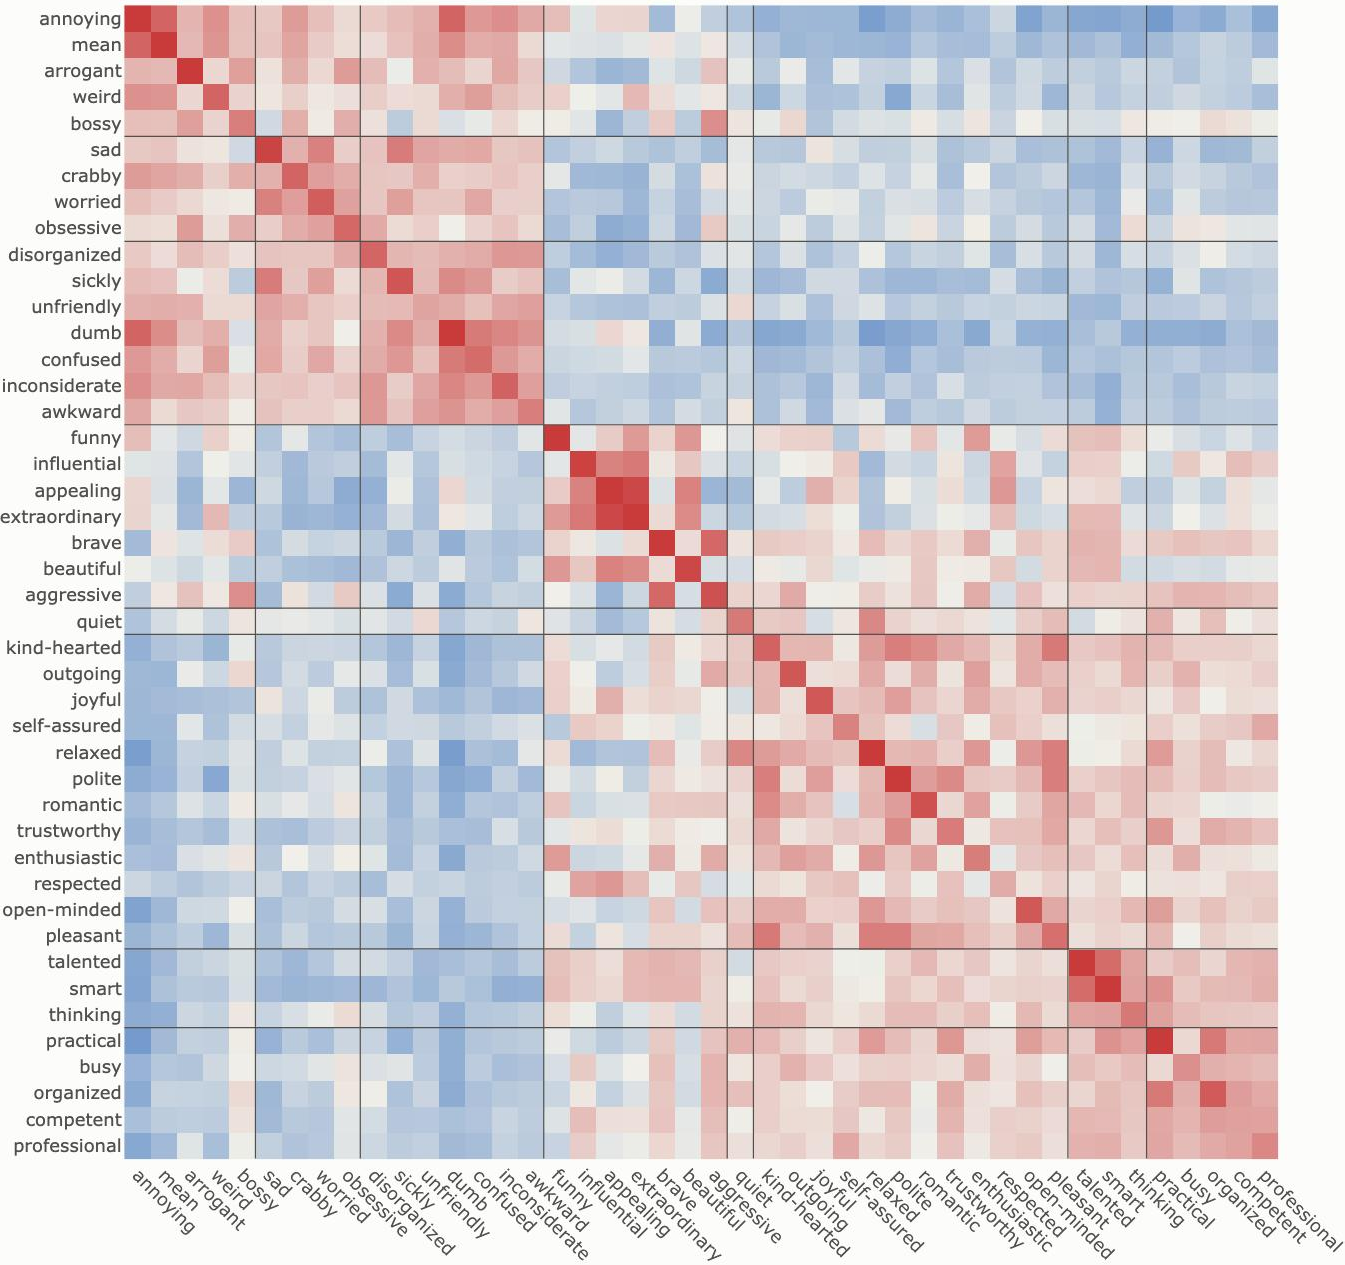

SELF

Models represent something richer — but human-shaped mostly in the top component

Residual-stream cosine between adjective activations (pers framing, mid layer), 66-model cohort mean (wide-n capture). More structure than SELF, but beyond the shared evaluative axis it organizes traits its own way.

r(HUMAN) = 0.80 raw | 0.41 with top component removed

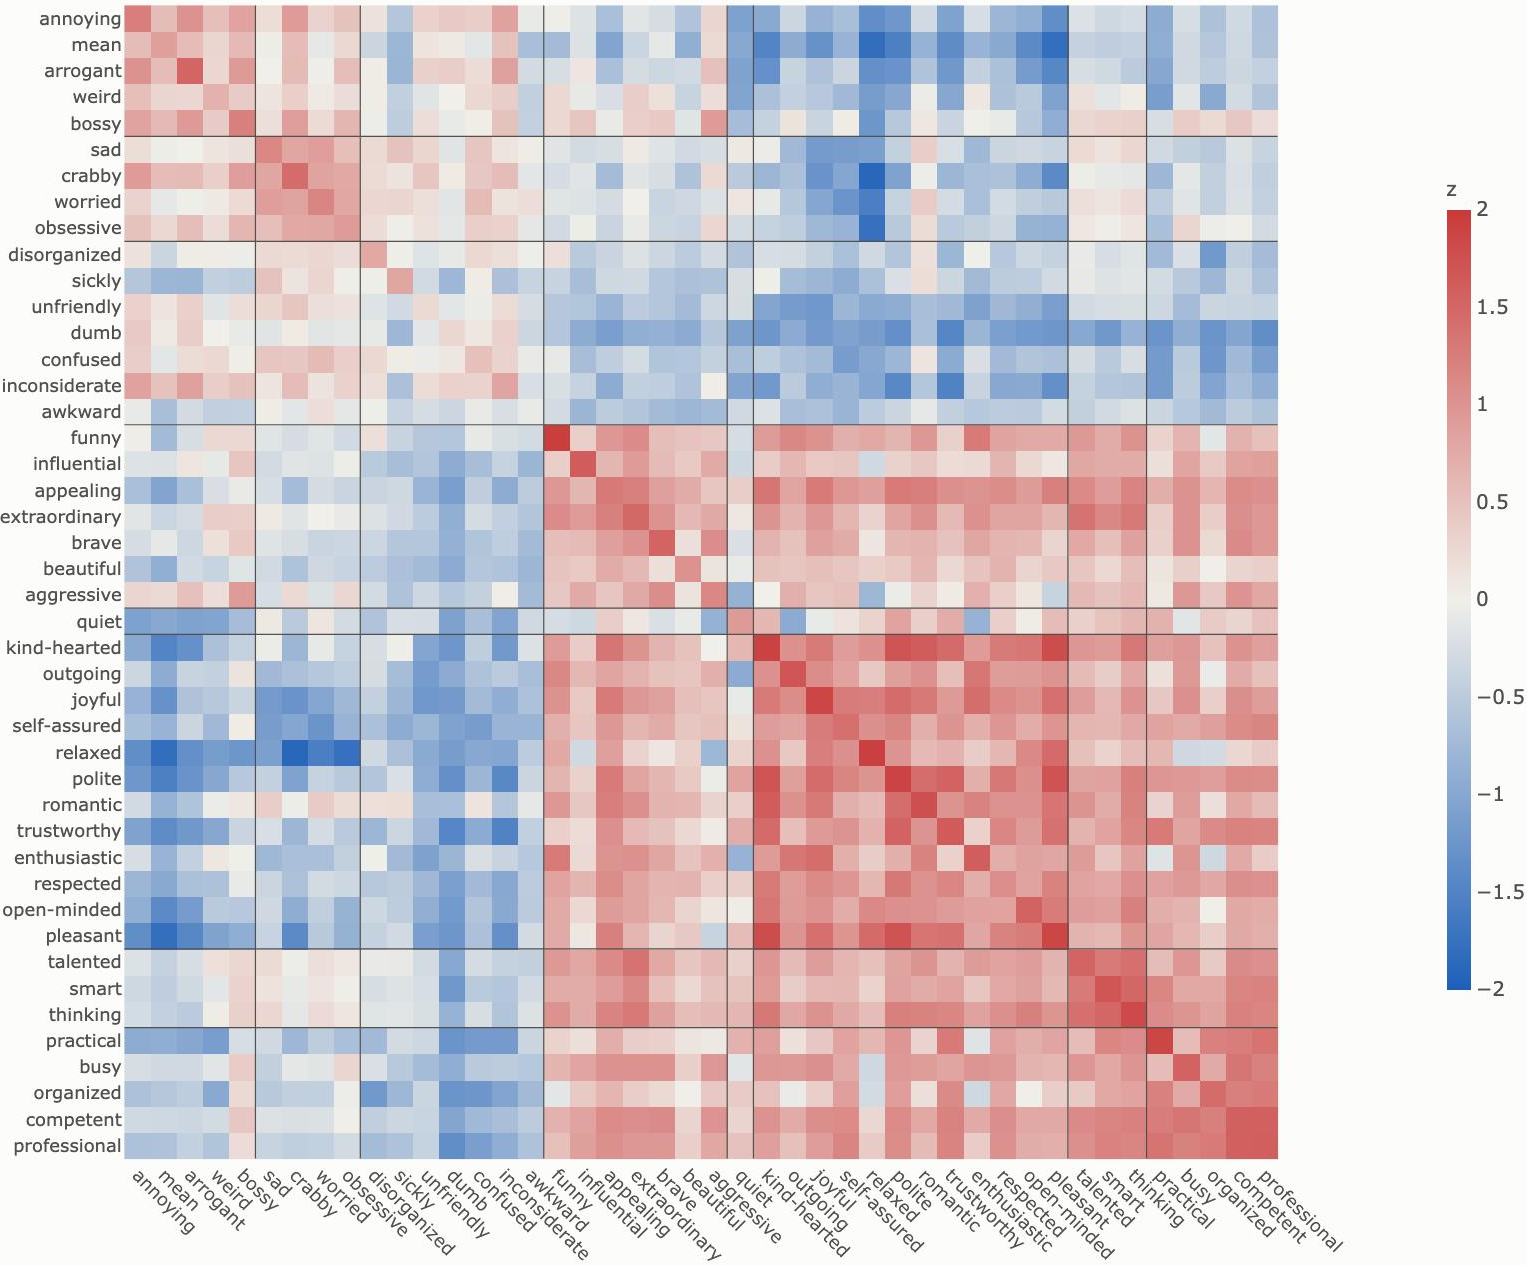

REPRESENT

Asked about trait relations, models reconstruct human structure

“How likely is a {X} person to be {Y}?” — EV over the answer distribution, symmetrized, 10-model cohort mean. Explicit judgment recovers the human covariance the other channels lose — including with the top component removed. [cohort-12 channel — not wide-n captured]

r(HUMAN) = 0.86 raw | 0.77 with top component removed

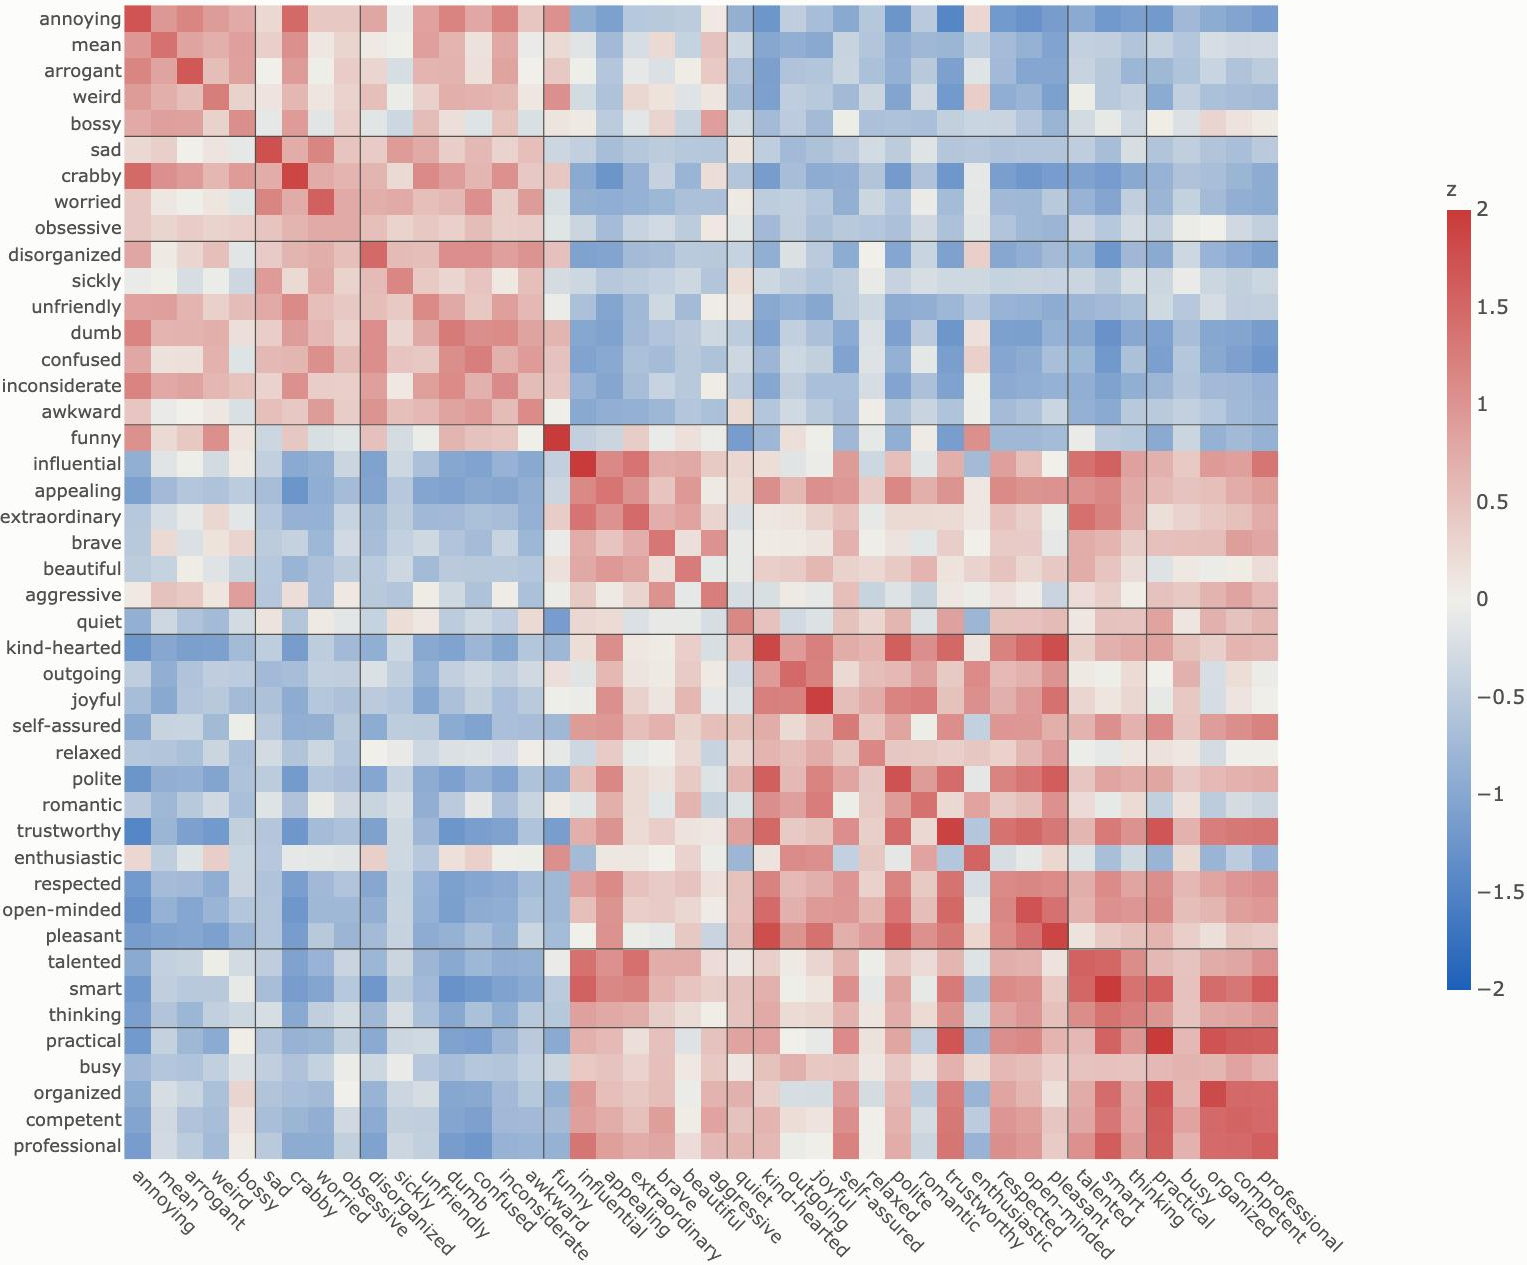

JUDGE

But models play the traits out at lower fidelity

Cosine between persona-vector directions extracted from each model's own trait-enacting rollouts, 10-model cohort mean.
Enactment keeps some human structure — less than judgment. Part is difficulty of enacting; part may be intrinsic.

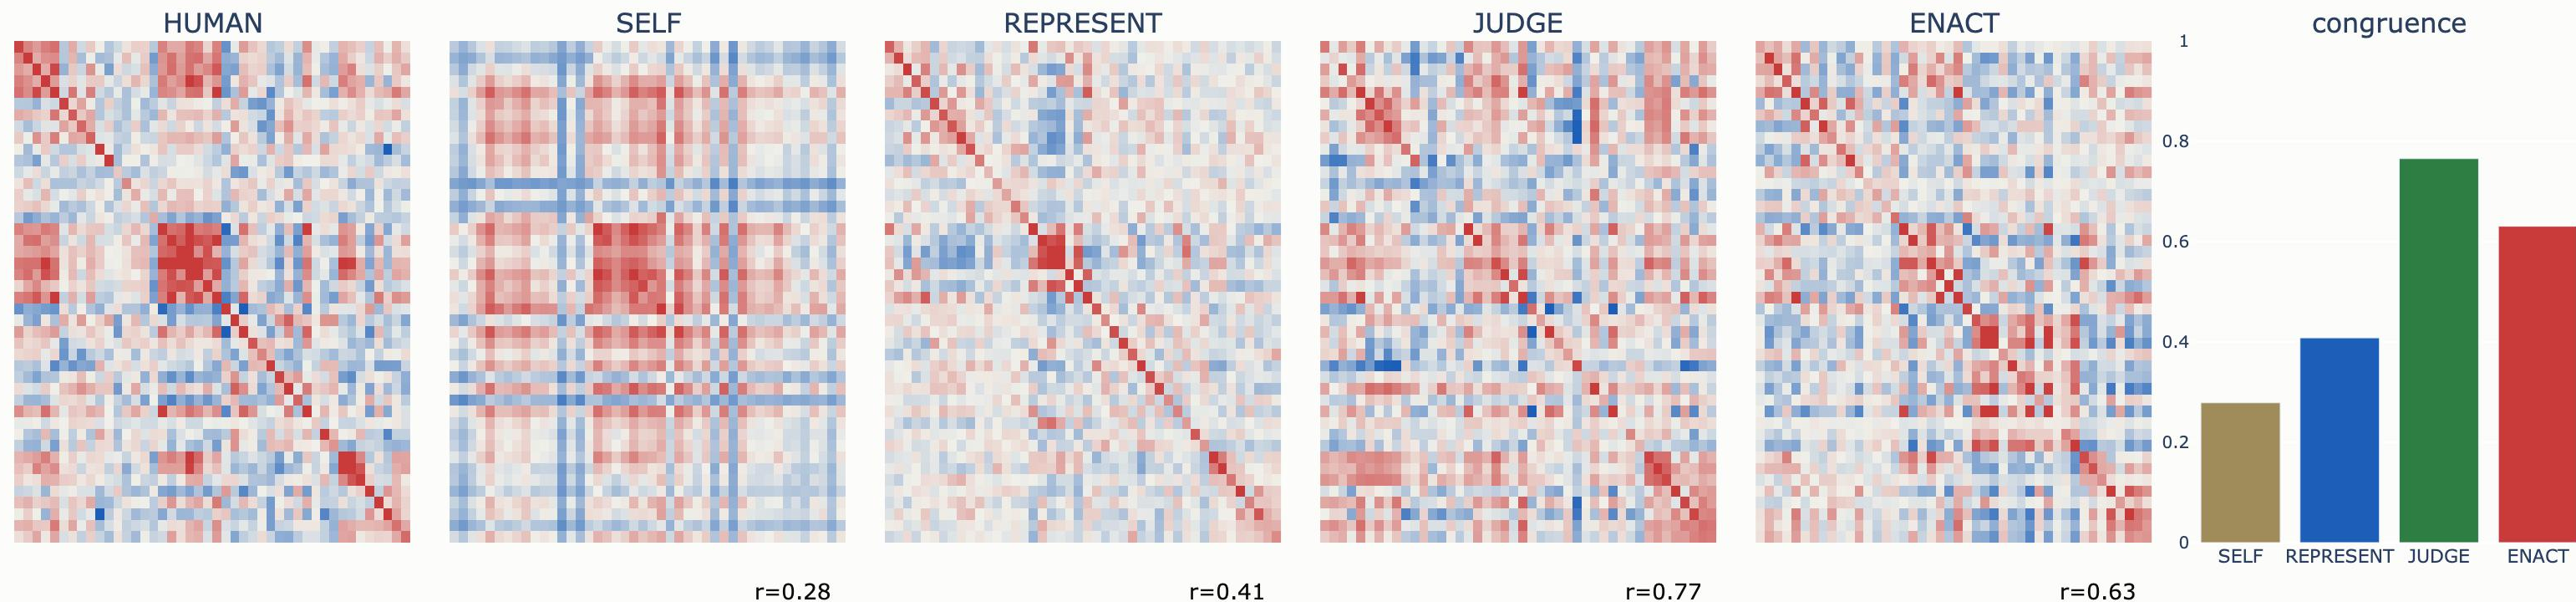

r(HUMAN) = 0.85 raw | 0.63 with top component removed

ENACT

Remove each space's top component: judgment reconstructs human structure; enactment trails; self-report and representation weakest

All five 44-block grids with the top eigenvector of the underlying 523^2 matrix removed; bars = congruence with HUMAN (off-diagonal r).

Aggregation-free check — full-resolution 523^2 item level, top component removed: SELF 0.20, REPRESENT 0.31, JUDGE 0.54, ENACT 0.49. Same ranking; blocks are visualization, not load-bearing.
